Background: Trauma assessment clinics (TAC) have been proposed over the past decade as a solution to the high volume of patients attending traditional fracture out-patient appointments. In the wake of coronavirus disease 2019 (COVID-19) guidelines from the Health Service Executive (HSE) and British Orthopaedic Association (BOA) were given recommending a reduction in the number of out-patient appointments, where appropriate.

Methods: Following introduction of a virtual TAC in collaboration between Emergency Department (ED) staff and the Orthopaedic Department at a large tertiary trauma centre, we looked at the number of out-patient clinic attendances avoided and time to in-person fracture clinic appointments from presentation to ED.

Results: From a fracture clinic perspective, 33% of patients were discharged directly with no follow up required. For the remaining patients the average time to outpatient attendance changed from 7 days (average prior to TAC) to 17 days. This reduction resulted in 1 less patient attendance in the fracture clinic per patient. Following our first 6 weeks of data collection, the proforma was altered to encourage specific collection of information and increase accessibility and quality of data collected for both departments.

Conclusions: Introduction of TAC allowed the Orthopaedic department to reduce out-patient attendances during the COVID pandemic, in line with guidelines. With our proforma ED staff may reduce time taken to manage these patients and also reduce re-attendance at ED for the same injury. Change in trends following proforma alteration allows us to propose a specific and detailed proforma which could be used by other hospitals or departments in the introduction of virtual clinics.

Keywords: Virtual fracture clinic (VFC); trauma assessment clinic (TAC); fracture clinic; trauma assessment clinic proforma; emergency department attendance
